Imaging and Deconvolution

Urvashi Rau

National Radio Astronomy Observatory, Socorro, NM, USA
An interferometer is an indirect imaging device.

Young’s double slit experiment:

- Light waves
- Barrier
- Interference pattern

2D Fourier transform:

Image = sum of cosine 'fringes'.

Each antenna-pair measures the parameters of one 'fringe'.

Parameters of a Fringe:
- Amplitude, Phase
- Orientation, Wavelength
The van-Cittert Zernike theorem

Measure the spatial correlation of the E-field incident at each pair of antennas

\[ \langle E_i E_j^* \rangle \propto V_{ij}(u, v) = \iint I^{\text{sky}}(l, m) e^{2\pi i (ul + vm)} \, dl \, dm \]

Parameters of a Fringe:
- Amplitude, Phase: \( \langle E_i E_j^* \rangle \) is complex.
- Orientation, Wavelength: \( \vec{u}, \vec{v} \) (geometry)

Sky Brightness (RA – DEC coordinates)

Visibility Function (Spatial Freq. coordinates)
Aperture Synthesis

Measure many (different) fringes : As much of $V(u, v)$ as possible

→ Multiple antenna pairs  → Multiple times  → Multiple observing frequencies

Length and orientation of the vector between two antennas, projected onto the plane perpendicular to the line of sight.

Spatial Frequency :

Image is real => Visibility function is Hermitian : $V(u, v) = V^*(-u, -v)$

For each antenna pair, $u, v$ change with time (hour-angle, declination) and observing frequency.

Time and Frequency-resolution of the data samples $\delta \tau, \delta \nu$ decides $\delta u, \delta v$

$\Rightarrow$ One baseline : 2 visibility points
Spatial Frequency (uv) coverage + Observed Image

\[
\begin{bmatrix}
u \\
v \\
w
\end{bmatrix} = \frac{1}{\lambda} \begin{bmatrix} R(h, \theta) \\ \delta x \\ \delta y \\ \delta z \end{bmatrix}
\]

Image of the sky using 2 antennas

\[I^{\text{obs}}(l, m)\]
Spatial Frequency (uv) coverage + Observed Image

\[
\begin{bmatrix}
  u \\
  v \\
  w
\end{bmatrix} = \frac{1}{\lambda} \begin{bmatrix}
  R(h, \theta) \\
  \delta x \\
  \delta y \\
  \delta z
\end{bmatrix}
\]

Image of the sky using 5 antennas

\[
S(u, v)
\]

\[
I^{obs}(l, m)
\]
Spatial Frequency (uv) coverage + Observed Image

\[
\begin{bmatrix}
  u \\
  v \\
  w
\end{bmatrix} = \frac{1}{\lambda} \begin{bmatrix}
  R(h, \theta) \\
  \delta x \\
  \delta y \\
  \delta z
\end{bmatrix}
\]

Image of the sky using 11 antennas

\[ S(u, v) \]

\[ I_{\text{obs}}(l, m) \]
Spatial Frequency (uv) coverage + Observed Image

\[
\begin{bmatrix}
  u \\
  v \\
  w \\
\end{bmatrix} = \frac{1}{\lambda} \begin{bmatrix}
  R(h, \theta) \\
  \delta x \\
  \delta y \\
  \delta z \\
\end{bmatrix}
\]

Image of the sky using 27 antennas

\[
S(u, v)
\]

\[
I_{\text{obs}}^{\text{obs}}(l, m)
\]
Spatial Frequency (uv) coverage + Observed Image

\[
\begin{bmatrix}
  u \\
  v \\
  w
\end{bmatrix} = \frac{1}{\lambda}
\begin{bmatrix}
  \delta x \\
  \delta y \\
  \delta z
\end{bmatrix}
\]

Image of the sky using 27 antennas over 2 hours 'Earth Rotation Synthesis'

\[ S(u,v) \]

\[ I^{obs}(l,m) \]
Spatial Frequency (uv) coverage + Observed Image

\[
\begin{bmatrix}
  u \\
  v \\
  w
\end{bmatrix} = \frac{1}{\lambda} \begin{bmatrix}
  \delta x \\
  \delta y \\
  \delta z
\end{bmatrix} R(h, \theta)
\]

Image of the sky using 27 antennas over 4 hours 'Earth Rotation Synthesis'

\(S(u, v)\)

\(I^{obs}(l, m)\)
Spatial Frequency (uv) coverage + Observed Image

\[
\begin{bmatrix}
u \\
v \\
w
\end{bmatrix} = \frac{1}{\lambda} \begin{bmatrix}
\delta x \\
\delta y \\
\delta z
\end{bmatrix} R(h, \theta)
\]

Image of the sky using 27 antennas over 4 hours, 2 freqs 'Multi-Frequency Synthesis'

\[S(u, v)\]

\[I^{obs}(l, m)\]
Spatial Frequency (uv) coverage + Observed Image

\[
\begin{bmatrix}
  u \\
  v \\
  w
\end{bmatrix} = \frac{1}{\lambda} \begin{bmatrix}
  R(h, \theta) \\
  \delta x \\
  \delta y \\
  \delta z
\end{bmatrix}
\]

Image of the sky using 27 antennas over 4 hours, 3 freqs 'Multi-Frequency Synthesis'

\[S(u, v)\]

\[I_{\text{obs}}^{\text{J2000}}(l, m)\]
Image formed by an interferometer: Convolution Equation

\[ I^{\text{obs}}(l, m) = I^{\text{PSF}}(l, m) \ast I^{\text{sky}}(l, m) \]

=> You have measured the Convolution of the True Sky with the instrumental PSF.

=> Recovering the True Sky \(\rightarrow\) DE-convolution

First Step: Construct the PSF image, and the OBSERVED image...
The PSF is

--- the impulse-response of the instrument ( image of a point-source )

--- the intensity of the diffraction pattern through an array of 'slits' ( dishes )

--- a measure of the imaging-properties of the instrument

\[
S(u, v)
\]

\[
I^{psf}(l, m) = F^{-1}[S(u, v)]
\]
- **Choosing image 'cell' size**: Nyquist-sample the main lobe of the PSF

  \[
  \text{PSF beam width} \cdot \frac{\lambda}{b_{\text{max}}} = \frac{1}{u_{\text{max}}} \quad \text{radians} \quad (\times \frac{180}{\pi} \text{ to convert to degrees})
  \]

  This is the diffraction-limited angular-resolution of the telescope
  
  Ex: Max baseline: 10 km. Freq = 1 GHz. Angular resolution: 6 arcsec

- **Choosing image field-of-view** (npixels): As much as desired/practical.

  \[
  \frac{1}{\text{fov}_{\text{rad}}} = \delta u
  \]

  Field of View (fov) controls the \textbf{uv-grid-cell size} \((\delta u, \delta v)\)

  - Antenna primary-beam limits the field-of-view ( 'slits' of finite width )

- **Gridding + FFT**:

  - An interferometer measures irregularly spaced points on the UV-plane.
  - Need to place the visibilities onto a regular grid of UV-pixels, and then take an FFT
Imaging in practice: Gridding and Weighting

Visibility data are recorded onto a regular grid before taking an i-FFT. Convolutional Resampling involves using a gridding convolution function and applying weights per visibility (weighted average of all data points per cell).

- Natural Weights:
  \[
  \begin{array}{cccc}
  1 & 1 & 1 \\
  1 & 2 & 2 & 1 \\
  2 & 3 & 2 & 2 \\
  2 & 2 & 1 \\
  1 & 1 & 1 \\
  \end{array}
  \]

- Uniform Weights:
  \[
  \begin{array}{cccc}
  1 & 1 & 1 \\
  1 & 1 & 1 \\
  1 & 1 & 1 \\
  1 & 1 & 1 \\
  1 & 1 & 1 \\
  \end{array}
  \]
Imaging in practice: Weighting schemes

An Image is a weighted average of the data.

Weighting-scheme => modify the imaging properties of the instrument
=> emphasize features/scales of interest
=> control imaging sensitivity

<table>

Note the noise-structure. Noise is correlated between pixels by the PSF. Image Units (Jy/beam)

All pairs of images satisfy the convolution relation => Need to deconvolve them
Iterative Image Reconstruction – Major and Minor Cycles

**Major Cycle**
- **Imaging**
  - **Gridding**
    - Use Flags and Weights
  - iFFT

**Minor Cycle**
- **Deconvolution**
  - FFT
  - De-gridding

**Data** → **Model** → **Residual** → **Residual Image**

**Model Image**
Deconvolution – Hogbom CLEAN

Sky Model: List of delta-functions

1. Construct the observed (dirty) image and PSF
2. Search for the location of peak amplitude.
3. Add a delta-function of this peak/location to the model
4. Subtract the contribution of this component from the dirty image - a scaled/shifted copy of the PSF

Repeat steps (2), (3), (4) until a stopping criterion is reached.

5. Restore: Smooth the model with a 'clean beam' and add residuals

The CLEAN algorithm can be formally derived as a model-fitting problem

- model parameters: locations and amplitudes of delta functions
- solution process: $\chi^2$ minimization via an iterative steepest-descent algorithm (method of successive approximation)
Multi-Scale Sky Model: Linear combination of 'blobs' of different scale sizes

- Efficient representation of both compact and extended structure (sparse basis)

A scale-sensitive algorithm

1. Choose a set of scale sizes

2. Calculate dirty/residual images smoothed to several scales (basis functions)
   - Normalize by the relative sum-of-weights (instrument's sensitivity to each scale)

3. Find the peak across all scales, update a single multi-scale model as well as all residual images (using information about coupling between scales)

Iterate, similar to Classic CLEAN, and restore at the end.

The MS-CLEAN algorithm can also be formally derived as a model-fitting problem using $\chi^2$ minimization and a basis set consisting of several 'blob' sizes.
## Deconvolution – Comparison of Algorithms

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

Image Quality

**Noise in the image**: Measured from restored or residual images

- With perfect reconstruction,
  The ideal noise level is: \( RMS \propto \frac{T_{sys}}{\eta_a} \sqrt{N_{ant}(N_{ant}-1) \cdot \delta \tau \cdot \delta \nu \cdot N_{pol}} \)

- In reality, measure the RMS of residual pixel amplitudes

**Dynamic Range**: Measured from the restored image

- Standard: Ratio of peak brightness to RMS noise in a region devoid of emission.
- More truthful: Ratio of peak brightness to peak error (residual)

**Image Fidelity**: Correctness of the reconstruction

- remember the infinite possibilities that fit the data perfectly?
- useful only if a comparison image exists.

Inverse of relative error: \( \frac{I_m \ast I_{beam}}{I_m \ast I_{beam} - I_{restored}} \)
How can you control the quality of image reconstruction?

(1) Iterations and stopping criterion

'niter' : maximum number of iterations / components
'threshold' : don't search for flux below this level

- minor cycles can be inaccurate, so periodically trigger major cycles

(2) Using masks

Need masks only if the deconvolution is “hard”.
  => Bad PSFs with high sidelobes
  => Leftover bad data causing stripes or ripples
  => Extended emission with sharp edges
  => Extended emission that is seen only by very few baselines

Draw interactively (start small, and grow them) or supply final mask.

(3) Self-Calibration

Use your current best estimate of the sky ( i.e. the model image ) to get new antenna gain solutions. Apply, Image again and repeat.
Wide-band Imaging – Sensitivity and Multi-Frequency Synthesis

<table>
<thead>
<tr>
<th>Frequency Range</th>
<th>(1 – 2 GHz)</th>
<th>(4 – 8 GHz)</th>
<th>(8 – 12 GHz)</th>
</tr>

<td>$(\nu_{\text{max}} - \nu_{\text{min}})/\nu_{\text{mid}}$</td>
<td>66%</td>
<td>66%</td>
</tr>
</tbody>
</table>

UV-coverage / imaging properties change with frequency

Sky Brightness can also change with frequency → model intensity and spectrum
Spectral Cube (vs) MFS imaging

3 flat-spectrum sources + 1 steep-spectrum source (1-2 GHz VLA observation)

Images made at different frequencies (limited to narrow-band sensitivity)

Add all single-frequency images (after smoothing to a low resolution)

Use wideband UV-coverage, but ignore spectrum (MFS, nterms=1)

Use wideband UV-coverage + Model and fit for spectra too (MT-MFS, nterms > 1)

Output: Intensity and Spectral-Index
Wide-Field Imaging – W-term

\[ V_{obs}(u, v) = S(u, v) \iint I(l, m) e^{2\pi i (ul + vm)} \, dl \, dm \]

\[ V_{obs}(u, v) = S(u, v) \iiint I(l, m) e^{2\pi i (ul + vm + wn - 1)} \, dl \, dm \, dn \]

The 'w' of a baseline can be large, away from the image phase center.
The 'n' for a source can be large, away from the image phase center.

2D Imaging
Facet Imaging
W-Projection
Wide-Field Imaging – Primary Beams

Each antenna has a limited field of view => Primary Beam (gain) pattern

=> Sky is (approx) multiplied by PB, before being sampled by the interferometer

\[ I_{\text{obs}}(l,m) \approx I^{\text{PSF}}(l,m) \ast [P^{\text{sky}}(l,m) \cdot I^{\text{sky}}(l,m)] \]

The antenna field of view:
\[ D = \text{antenna diameter} \]
\[ \lambda/D \]

Compare with angular resolution of the interferometer:
\[ \lambda/b_{\text{max}} \]

But, in reality, P changes with time, freq, pol and antenna....

=> Ignoring such effects limits dynamic range to \(10^4\)

=> More-accurate method to account for this: A-Projection
Wide-field Imaging -- Mosaics

Combine data from multiple pointings to form one large image.

Combine pointings either before or after deconvolution.

**Stitched mosaic:**

- Deconvolve each pointing separately
- Divide each image by PB
- Combine as a weighted avg

**Joint mosaic:**

- Combine observed images as a weighted average
  (or)
  Grid all data onto one UV-grid, and then iFFT
- Deconvolve as one large image

One Pointing sees only part of the source
Wide-field Imaging -- Mosaics

Combine data from multiple pointings to form one large image.

Combine pointings either before or after deconvolution.

**Stitched mosaic:**

-- Deconvolve each pointing separately
-- Divide each image by PB
-- Combine as a weighted avg

**Joint mosaic:**

-- Combine observed images as a weighted average
  (or)
  Grid all data onto one UV-grid, and then iFFT
-- Deconvolve as one large image

Two Pointings see more.....
Wide-field Imaging -- Mosaics

Combine data from multiple pointings to form one large image.

Combine pointings either before or after deconvolution.

**Stitched mosaic:**
- Deconvolve each pointing separately
- Divide each image by PB
- Combine as a weighted avg

**Joint mosaic:**
- Combine observed images as a weighted average
  (or)
  Grid all data onto one UV-grid, and then iFFT
- Deconvolve as one large image

Use many pointings to cover the source with approximately uniform sensitivity.
Some points to remember ...

How does an interferometer form an image?

- Each antenna pair measures one 2D fringe.
  Many antenna pairs => Fourier series

How do you make a raw image from interferometer data?

- Assign weights to visibilities, grid them, take a Fourier transform

How do you choose the cell-size and image size for imaging?

- Cell size = ( Resolution / 3 ). Image size = field-of-view / cell size

What does the raw observed image represent?

- Observed Sky is the convolution of the true sky and the PSF

How do you get a model of the sky?

- Solve the convolution equation via algorithms like Clean, MS-Clean, MT-Clean...
Some points to remember ...

How do you measure image quality?
- RMS noise, Peak residual, Dynamic range, Image fidelity

How does wide-band data affect the imaging process?
- Increased sensitivity, but the imaging properties and sky change with frequency

How do you image wide-band data?
- Make a Cube of images, or Multi-Frequency-Synthesis with a spectral fit.

What is an antenna primary beam and what is its effect on an image?
- Antenna power pattern. It multiplies with the sky, before convolution with the PSF

What is the w-term problem?
- 2D Fourier transform approximations are invalid far away from the image center
Example Imaging Problem – Simulated data

Simulated 5 GHz observation with a 13-antenna array over 5 hours

N visibilities : 9360. Visibility noise : 2 Jy  =>  Theoretical image RMS : 0.02 Jy

Angular resolution : 5 arcsec  ( Max baseline of 2500m at 5.0 GHz )
Sky brightness has compact and extended structure (partially-sampled).
Peak brightness : 1 Jy  =>  Target dynamic range = 50

\[ I^{\text{sky}}(l, m) \]

\[ S(u, v) \]

\[ V^{\text{sky}}(u, v) \cdot S(u, v) \]
Example Imaging Problem – First try....

Quick deconvolution with different weighting schemes:

- **Image FOV**: 7 arcmin (512 pixels at 0.8 arcsec pixel size)
- **MS-CLEAN**: NIter=100, scales=[0,6,40], gain=0.3, robust=0.7

---

**Natural**: High sidelobes

**Robust = 0.7**: Uniform with only SHORT Baselines < 500m

**Uniform**: Low sensitivity to extended emission

Uniform with only LONG Baselines > 500m

(Extended structure disappears)
Example Imaging Problem – Second try...

Make a larger image  ( 700 pixels at 0.8 arcsec cell size )

N Iter = 0 (dirty image )
Pick scales = [0,6,16,30,42,60]
Weighting : Robust=0.7
Loop gain = 0.2
  ( go slow, because of insufficient data-constraints for the extended emission )

Peak sidelobe structure : 0.2 Jy/beam.  Off-source RMS : 0.1 Jy/beam
Peak brightness : 1 Jy/beam  =>  Dynamic Range : 10 ~ 20
After 100 iterations.

Restored Image

Residual Image

Peak sidelobe structure : 0.1 Jy/beam. Off-source RMS : 0.05 Jy/beam
Peak brightness : 1 Jy/beam => Dynamic Range : 10 ~ 20
Example Imaging Problem – Second try...

After 500 iterations. Almost OK. Spurious extended flux in the upper-left. No counterpart in the residual image => large scales unconstrained by the data.

**Restored Image**

Peak artifacts : 0.07 Jy/beam.  Off-source RMS : 0.02 Jy/beam  Peak brightness : 1 Jy/beam  =>  Dynamic Range : 14 ~ 50

- Reached theoretical off-source RMS of 0.02 Jy/beam. But peak residual is still high.
Example Imaging Problem – Using masks

Build 'CLEAN boxes' or masks and restart. This will force extended emission to be centered within the allowed regions only.

In general, point sources do not require boxes. Extended emission needs it only if data constraints are insufficient.
After 300 iterations (compared to 500 earlier) – Reached theoretical rms and dynamic-range!

Peak sidelobe structure: 0.04 Jy/beam.  Off-source RMS: 0.02 Jy/beam

Peak brightness: 1 Jy/beam => Dynamic Range: 25 ~ 50
